

# Foreword

## How Forecasts Are Made

Most of the annual streamflow in the Western United States originates as snowfall. This snowfall accumulates high in the mountains during winter and early spring. As the snowpack accumulates, hydrologists estimate the runoff that will occur when it melts. Predictions are based on careful measurements of snow water equivalent at selected index points. Precipitation, temperature, soil moisture and antecedent streamflow data are viewed in conjunction with snowpack data to prepare runoff forecasts. This report presents a comprehensive picture of water supply outlook conditions for areas dependent upon surface runoff. It includes selected streamflow forecasts, summarized snowpack and precipitation data, reservoir storage data and narratives describing current conditions.

Streamflow forecasts are cooperatively generated by Soil Conservation Service and National Weather Service hydrologists. Forecasts become more accurate as more data affecting runoff becomes known. For this reason, forecasts are issued that reflect three future precipitation conditions — Below Normal, Average, and Above Normal. These forecasts are termed reasonable minimum, most probable, and reasonable maximum. Actual streamflow can be expected to fall between the lower and upper forecast values eight out of ten years.

Snowpack data are obtained by using a combination of manual and automated measurement methods. Manual readings of snow depth and water equivalent are taken at locations called snow courses on a monthly or semi-monthly schedule during the winter. In addition, snow water equivalent, precipitation, temperature, and other parameters are monitored on a daily basis and transmitted via radio telemetry to central data collection facilities. Both monthly and daily data are used to project snowmelt runoff.

## For More Information

Copies of Monthly Water Supply Outlook Reports and other reports may be obtained from the states listed below. Because of the limited space, snow survey measurements are not published in monthly reports. An annual snow survey data summary is published by the Soil Conservation Service for each of the western states. Historical snow survey data may be obtained at those same offices.

STATE	ADDRESS
Alaska	201 East 9th Ave., Suite 300, Anchorage, AK 99501-3687
Arizona	201 East Indianola, Suite 200, Phoenix, AZ 85012
Colorado (New Mexico)	2490 West 26th Ave., Denver, CO 80211
Idaho	304 North 8th Street, Room 345, Boise, ID 83702
Montana	10 East Babcock, Room 443, Federal Building, Bozeman, MT 59715
Nevada	50 South Virginia Street, Third Floor, Reno, NV 89505
Oregon	1220 Southwest 3rd Ave., 16th Floor, Portland, OR 97204
Utah	4402 Federal Building, 125 South State Street, Salt Lake City, UT 84147
Washington	360 U.S. Court House, Spokane, WA 99201
Wyoming	Federal Building, 100 East "B" Street, Casper, WY 82602

In addition to state reports, a Water Supply Outlook for the Western United States is published by the Soil Conservation Service and National Weather Service monthly, January through May. Reports may be obtained from the Soil Conservation Service, West National Technical Center, 511 Northwest Broadway, Room 547, Portland, OR 97209.

# STREAMFLOW PROSPECTS FOR MONTANA

Spring and Summer Period

## GENERAL OUTLOOK

### SUMMARY:

Below average March precipitation and melt generated by warm temperatures have reduced the snowpack levels reported on March 1. Snowpacks in extreme southwest Montana and near the Montana-Wyoming border are near normal, but all other areas have below to well below average snow cover. Generally, the northern areas have the poorest snowpack. Many areas have less snowpack now than was measured a year ago. Temperatures and melt conditions seem to be about a month earlier than normal. Streamflows are forecast to be near to a little below average in the Jefferson, Madison and Yellowstone River drainages but below to well below average in other areas. Some streams with lower elevation headwaters have already reached their peak snowmelt runoff. Widespread irrigation water shortages are expected by late June to early July over most of the state for irrigators not having stored water.

### SNOWPACK:

Snowpack levels are about 10 percent less than reported on March 1. Warm temperatures created melt at low and mid-elevations. Also, mountain precipitation was below average in all areas. Snowpack is well below average in northern areas increasing to below average through most of central Montana. The only areas reporting near average snowpack are along the Continental Divide from southwest of Helena to Yellowstone National Park, throughout most of the Yellowstone River headwaters and in the headwaters of the Clarks Fork of the Yellowstone, Bighorn, Little Bighorn, Tongue and Powder Rivers in Wyoming.

### PRECIPITATION:

Mountain precipitation during March was generally about 60 to 70 percent of average over most of the state. The lower Clark Fork area, west of Missoula, was a little better but still only around 90 percent of average. The St. Mary and Milk River headwaters also reported about 80 percent of average moisture in March. Many valley locations recorded well below average precipitation for the month. If the weather patterns do not improve, Montana can expect another dry spring and summer. For some areas, this could be the fifth consecutive year of below average precipitation.

## **RESERVOIRS:**

Most irrigation reservoirs across the state have average or above average storage due to good carryover from August and September rains and early season runoff that started in late February. Storage in most large and multipurpose reservoirs is near or above average.

## **STREAMFLOW:**

Except for average or above average runoff from streams with headwaters in Wyoming, below average streamflows are forecast for all streams and rivers in Montana. Well below average runoff is expected from streams in the Gallatin Valley and most streams in northwest and north central Montana. Except for areas in extreme southwest Montana and near the Montana-Wyoming border, most areas can expect shortages of irrigation water supplies by late June to early July. If above normal temperatures continue, runoff will occur earlier than usual and will create additional water shortage problems during the main irrigation season.

# Kootenai Basin

Mountain snowpack\* (Inches)

\* Kootenai in Montana

Precipitation\* (percent of normal)

\* Based on selected stations

## WATER SUPPLY OUTLOOK:

Snowpack conditions deteriorated in March as a result of below average mountain precipitation and melt created by warm temperatures. Snowpack is better in British Columbia than in Montana. Streamflow on the Kootenai River is forecast to be below average while tributary streams in Montana are predicted to have well below average runoff for the spring and summer months. Some smaller streams with low elevation headwaters may have already reached their peak snowmelt runoff.

For more information contact your local Soil Conservation Service office.

## WATER SUPPLY OUTLOOK:

Below average mountain precipitation and warmer temperatures during March have lowered snowpack percentages. Some higher elevations have fair snowpack but most areas including lower elevations have well below average amounts of snow cover. Spring and summer streamflows are forecast to be below average. Some low elevation streams have already had their peak snowmelt runoff.

## WATER SUPPLY OUTLOOK:

Snowpack conditions deteriorated in March. Below average mountain precipitation and above average melt dropped the snowpack 5 to 10 percent since March 1. The mountains around Butte and Anaconda have a little better snowpack than other areas. The Blackfoot has less snow than a year ago while the Clark Fork has about the same. Spring and summer runoff is expected to be 15 to 20 percent below average on most streams. Shortages of irrigation water supplies can be expected by late June or early July.

## WATER SUPPLY OUTLOOK:

Snowpack percentages have dropped about 10 percent since March 1. This is a result of below average mountain precipitation and melt caused by warm temperatures during March. There is less water stored in the snowpack than there was last year at this time. Spring and summer streamflows are forecast to be below average in all drainages. Shortages of irrigation water can be expected by late June to early July.

## WATER SUPPLY OUTLOOK:

Warm temperatures causing snowmelt and below average mountain precipitation during March combined to drop snowpack percentages about 10 percent since March 1. Snowpacks vary from near average to well below average. Spring and summer streamflows are forecast to be below average from all drainages. Shortages of irrigation water supplies can be expected by late June on lower elevation streams and by early July on most other drainages for those not having stored water.

For more information contact your local Soil Conservation Service office.

## WATER SUPPLY OUTLOOK:

Snowpack conditions deteriorated during March. Mountain precipitation for March was below average and melt was occurring at low and mid-elevations. The snowpack is presently well below average and less than it was a year ago. Spring and summer streamflows are forecast to be well below average on all drainages. Shortages of irrigation water supplies can be expected to develop by late June or early July for those users not having stored water.

For more information contact your local Soil Conservation Service office.

\* St. Mary

Precipitation\* (percent of normal)

\*Based on selected stations

## WATER SUPPLY OUTLOOK:

Below average March precipitation and warm temperatures reduced snowpack levels. Snow in mountains away from the Continental Divide has melted except for shaded high elevation areas. Spring and summer runoff is forecast to be well below average. However, reservoir storage is above average as a result of earlier runoff. Shortages of irrigation water supplies can be expected by mid to late June for those users not having stored water.

For more information contact your local Soil Conservation Service office.

## WATER SUPPLY OUTLOOK:

Snowpack deteriorated during March because of below average mountain precipitation and some snowmelt. Southern drainages have near average snowpack, decreasing to well below average in the northern drainages. Except for below average runoff from streams flowing out of the Crazy and Bridger Mountains, streamflows are expected to be near to a little below average. Irrigation water is expected to be short from streams out of the Crazy and Bridger Mountains but adequate elsewhere.

For more information contact your local Soil Conservation Service office.
